ONLINE FOOD ORDERING SYSTEM

Database Project using MySQL

Presented by: [Your Name]

Department: [Your Department / College]

Restaurants • Menu • Customers • Orders • Payments

1. Problem Statement

Based on the project brief

- Develop a database for an Online Food Ordering System.
- Enable customers to browse restaurant menus, place food orders, and make payments.
- Manage restaurant information, menu items, customer orders, and payment details.
- Support sales and order reports.

2. Project Objectives

- Maintain restaurant information and food menu details.
- Manage customer orders and track order status.
- Store payment method, amount, payment status, and date.
- Generate restaurant sales reports and customer order history.
- Identify popular food items.

3. Technologies Used

MySQL	SQL	GitHub
Database management system	Create, query, and manage data	Store and share project files

- The database is designed around five related tables.

4. ER Diagram

Five main entities in the project

Restaurants	Menu	Orders	Payments
restaurant_id (PK) restaurant_name location cuisine	menu_id (PK) restaurant_id (FK) item_name price availability	order_id (PK) customer_id (FK) menu_id (FK) quantity order_date order_status	payment_id (PK) order_id (FK) payment_method amount payment_status payment_date
		Customers customer_id (PK) customer_name phone city	

Relationships: Restaurants → Menu | Customers → Orders | Menu → Orders | Orders → Payments

5. Database Tables

Main columns from the project design

Table	Main columns
Restaurants	restaurant_id, restaurant_name, location, cuisine
Menu	menu_id, restaurant_id, item_name, price, availability
Customers	customer_id, customer_name, phone, city
Orders	order_id, customer_id, menu_id, quantity, order_date, order_status
Payments	payment_id, order_id, payment_method, amount, payment_status, payment_date

6. SQL Queries and Operations

- Retrieve restaurant, menu, customer, order, and payment information.
- Filter and sort records; use string and date functions.
- Use aggregate functions to count items and calculate totals or averages.
- Join related tables to show customer orders and restaurant revenue.
- Use views, transactions, stored procedures, and triggers where implemented.

Add screenshots of your actual query results before presenting.

7. Conclusion

- The project organizes core online food ordering data in a relational database.
- Relationships connect restaurants, menu items, customers, orders, and payments.
- SQL queries can help retrieve information and produce useful reports.
- Thank you.
